 (wetlands only)

Total catchment N retention for 117 catchments draining to the Baltic Sea calculated by combining the results from the MESAW and DAISY models.

# Future climate scenarios

- mean scenario (A1B)
- business-as-usual (A2)
- best case (B1)

## Runoff to Bothnian Sea

# Annual fluxes (Tg) of TC, DIC and DOC.

## 1996-2000 compared to 2090-2095

## 2) Challenge: Separate the terrestrial DOM from marine produced DOM

Terrestrial source  
(end member)  
 $\delta^{13}\text{C} = -28 \text{ ‰}$

Marine source  
(end member)  
 $\delta^{13}\text{C} = -21 \text{ ‰}$

$\delta^{13}\text{C} = -25 \text{ ‰}$

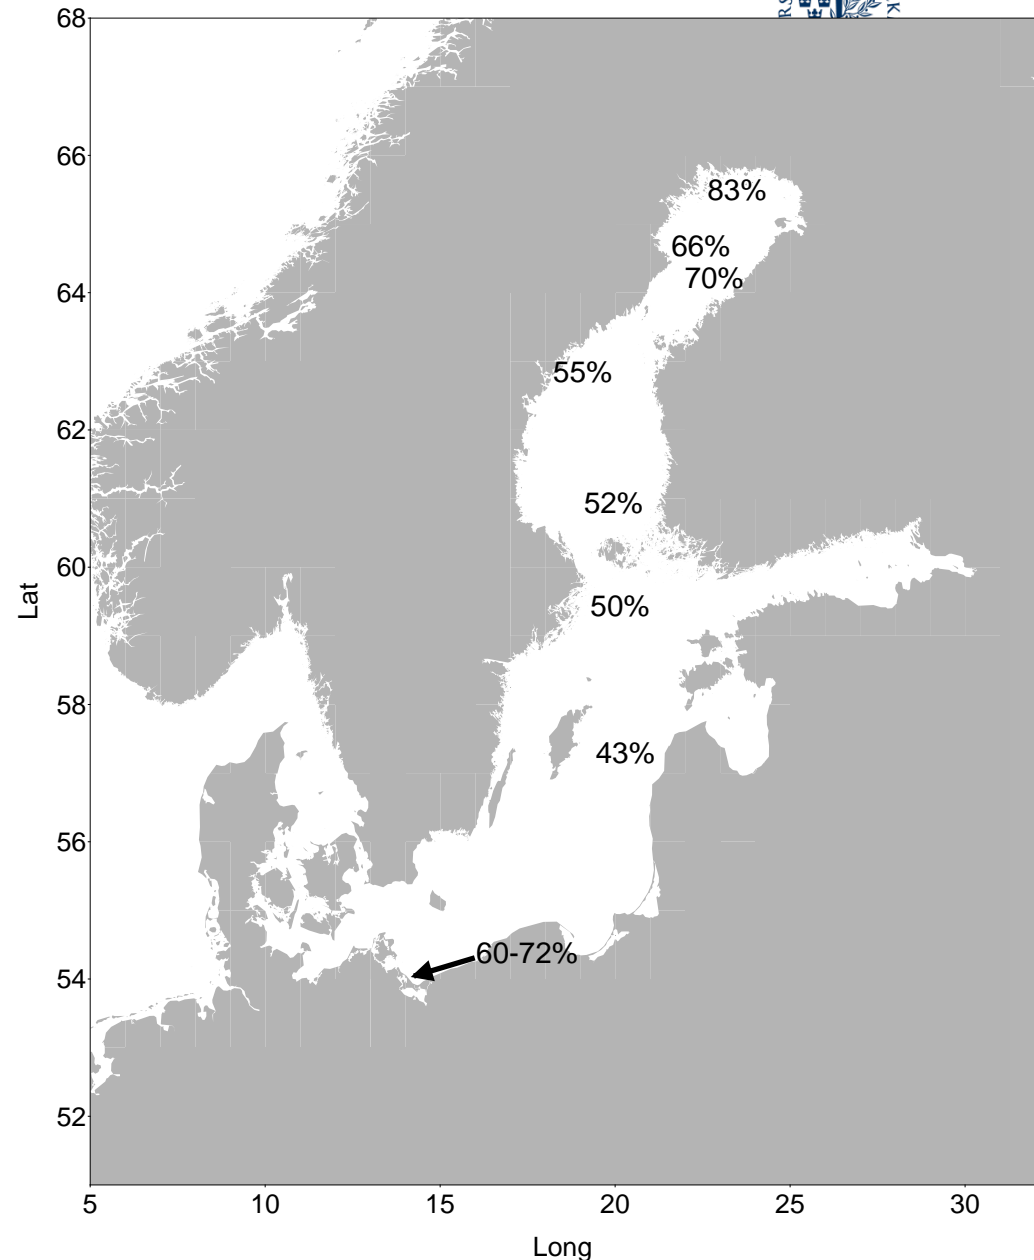

57 % terrestrial DOC 43 %  
marine

# Share of terrestrial DOC

Bothnian Bay:	70-83%
Bothnian Sea:	52-55%
Baltic Proper:	43-50%
Oder Bight:	60-72%

# Hypotheses based on studies on $\text{DOC}_{\text{ter}}$ inferred from isotope signatures

- At salinities  $>2$  the  $\text{DOC}_{\text{ter}}$  distribution along the Baltic seems to be determined mainly by mixing.
- Most of the  $\text{DOC}_{\text{ter}}$  removal ( $\sim 50\%$ ) seems to occur in the estuaries.

University

# WEGAS on board the German research vessel METEOR 87 (May/June 2012)

Changes in  $\delta^{13}\text{C}$  of  $\text{CO}_2$  during M87/3A, Transect A

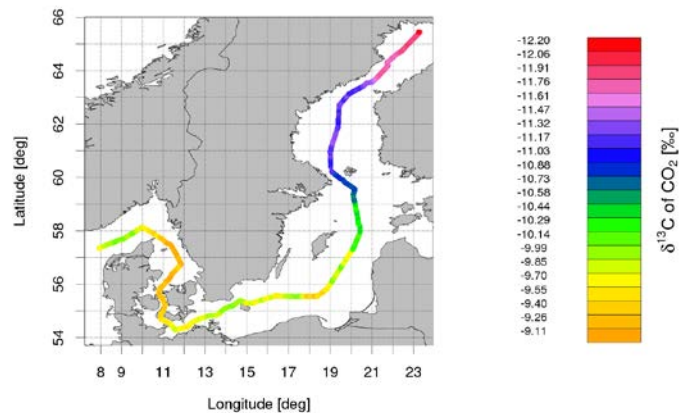

Changes in  $\delta^{13}\text{C}$  of  $\text{CO}_2$  during M87/3A, Transect A

$\text{CO}_2$  and  $\text{CH}_4$  concentrations in sea water measured by WEGAS (Stockholm University)

Changes in  $\delta^{13}\text{C}$  of  $\text{CO}_2$  during M87/3A, Transect A

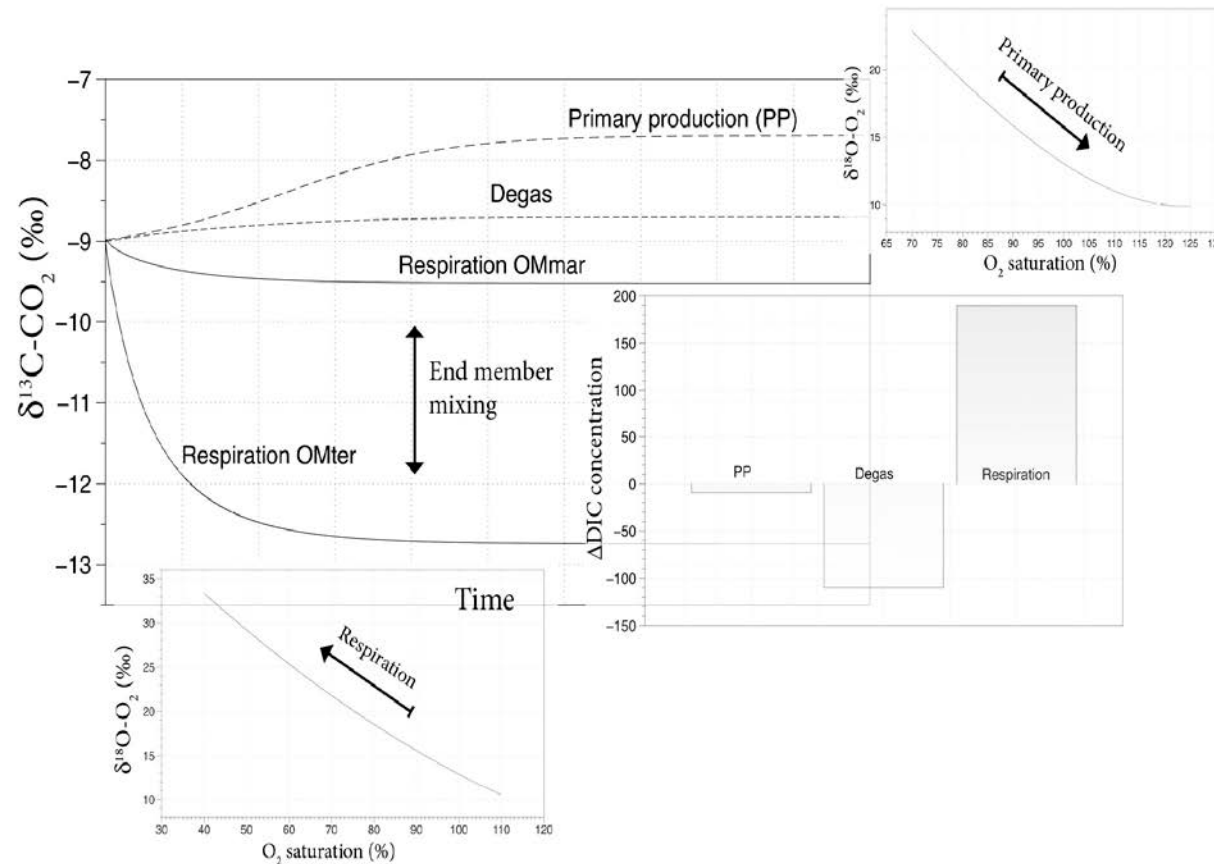

$\text{d}^{13}\text{C}$   $\text{CO}_2$  and  $\text{d}^{12}\text{C}$   $\text{CO}_2$  concentrations in sea water measured by WEGAS (Stockholm University)

# Conceptual model

Expected isotope patterns for  $\delta^{13}\text{C}$  in  $\text{CO}_2$  and  $\delta^{18}\text{O-O}_2$  dissolved in water as a result of the different processes that drive the fractionation of the isotopes in the different pools.

River input DOC/DIC

Salinity=0 PSU  
Alk=0.21 mmol/L  
DIC=0.25 mmol/L  
DOC=0.5 mmol/L  
PCO<sub>2</sub>=800 ppm

Needed respiration to maintain  
isotope value is  $\approx 32 \text{ mmol m}^{-2} \text{ per day}$   
 $\text{CO}_2 \approx -12.5\text{‰}$

Respiration  
 $\approx -27\text{‰}$

Production, isotope  
fractionation  $-13\text{‰}$

Salinity=1.5 PSU  
Alk=0.62 mmol/L  
DIC=0.65 mmol/L  
DOC=0.4 mmol/L  
PCO<sub>2</sub>=630 ppm

CO<sub>2</sub>sys gives air sea flux of  $\approx 20 \text{ mmol m}^{-2}$  degassing per day.

**Generally, both ERGOM and SCOBI give even lower simulated rates of PP!**

Hypoxia effects on nitrogen pool in the Baltic Proper. Relationships between annual means of simulated and reconstructed from observations hypoxic volume and DIN pool (A) or reconstructed DIN pool with a 2 year delay and simulated bioavailable nitrogen (B)

Dalsgaard et al. GCA 2013: “When extrapolated to the entire Baltic Proper (BP) denitrification in the water column was in the range of 132–547 kton N yr<sup>-1</sup> and was thus at least as important as sediment denitrification which has recently been estimated to 191 kton N yr<sup>-1</sup>.”

BONUS call 2012: Viable ecosystem  
Project: Biological lenses using gene prints  
(BLUEPRINT)

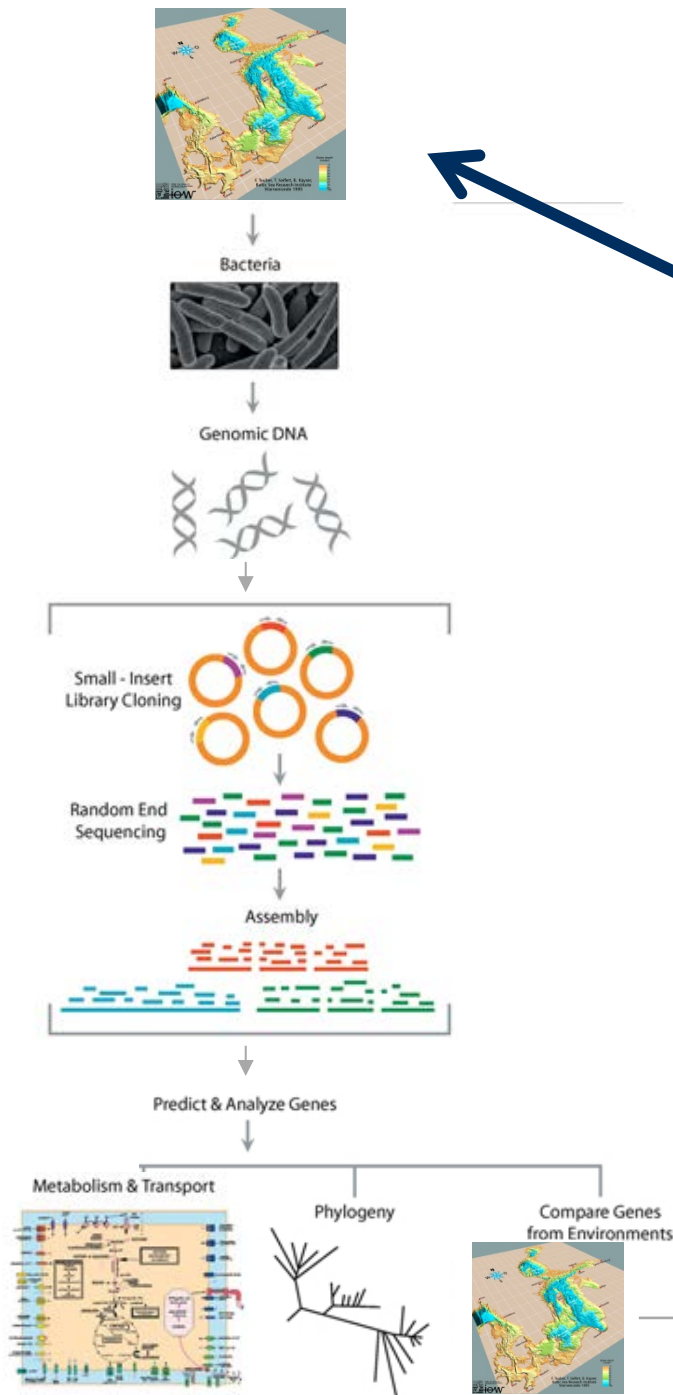

Stockholm  
University

**Aim:** Indicator development based on the generation of high-resolution functional databases throughout the Baltic Sea based on metagenomics.

**Outcome:** A publicly available resource with the capacity to deduce environmental status and dominant biogeochemical pathways from the biodiversity and genetic functional profiles of microbes, the blueprint, in a seawater sample.

# WP5: Incorporation of BLUEPRINT in biogeochemical modeling

**Metabolic chart**

# Outlook

Develop more realistic catchment (hydrological and land surface) models -> DOM and nutrient retention are the big unknowns!

Coastal degradation processes appear significant-> how much reaches the open Baltic?

To develop a general model to quantitatively link  $\text{CO}_2$  and  $\text{CH}_4$  fluxes from aquatic ecosystems to primary productivity, degradation and outgassing using new isotope techniques -> how much of the terrestrial respiration actually occurs in the sea?

Shed light on DOM dynamics in the Baltic Sea-> how it contributes to nutrient dynamics and PP?

DOM dynamics along the estuarine gradient in the Baltic play a similar important role as dissolved nutrient dynamics but is poorly parameterized in the models -> new microbiological tools needed?
